

Lecture 10 - Strings

Meng-Hsun Tsai
CSIE, NCKU

```
char s1[6] = {'H', 'e', 'l', 'l', 'o', '\0'};
```

```
char s2[6] = "Hello";
```

```
char s3[6] = "He" "llo";
```

H	e	l	l	o	\0
---	---	---	---	---	----

Introduction

- This lecture covers both *string constants* (or *literals*, as they're called *in the C standard*) and *string variables*.
- Strings are *arrays of characters* in which a *special character*—the *null character*—marks the end.
- The C library provides *a collection of functions* for *working with strings*.

10.1 String Literals

String Literals \Rightarrow " "

- A **string literal** is a sequence of characters enclosed within double quotes:
"When you come to a fork in the road, take it."
- String literals may contain escape sequences.
- Character escapes often appear in `printf` and `scanf` format strings.

- For example, each `\n` character in the string
"Candy\nIs dandy\nBut liquor\nIs quicker.\n --Ogden Nash\n"

causes the cursor to advance to the next line:

```
Candy
Is dandy
But liquor
Is quicker.
--Ogden Nash
```

Continuing a String Literal

- There are **two ways** to continue a string literal.
- The **backslash character (\)** can be **used to continue a string literal** from one line to the next:

```
printf("When you come to a fork in the road, take it. \  
--Yogi Berra");
```

- When **two or more string literals are adjacent**, the **compiler will join them into a single string**.
This rule **allows us to split a string literal over two or more lines**:

```
printf("When you come to a fork in the road, take it. "  
"--Yogi Berra");
```

How String Literals Are Stored

- When a C compiler encounters a string literal of length n , it sets aside $n + 1$ bytes of memory for the string.
- This memory will contain the characters in the string, plus one extra character—the **null character**—to mark the end of the string.
- The null character is a byte escape sequence whose bits are all zero, so it's represented by the `\0`.
- The string literal `"abc"` is stored as an array of four characters:

a	b	c	\0
---	---	---	----
- Similarly, the string `" "` is stored as a single null character:

\0

How String Literals Are Stored (cont.)

- Since a **string literal** is stored as an array, the **compiler treats it as a pointer of type `char *`**.
- Both `printf` and `scanf` **expect a value of type `char *` as their first argument**.
- The following call of `printf` passes the **address of `"abc"` (a pointer to where the letter `a` is stored in memory)**:

```
printf("abc");
```

Operations on String Literals

- We can use a string literal **wherever C allows a char * pointer:**

```
char *p;
```

```
p = "abc";
```

- This assignment makes **p point to the first character of the string.**

Operations on String Literals (cont.)

- String literals **can be subscripted**:

```
char ch;
```

```
ch = "abc"[1];
```

The new value of **ch** will be the letter **b**.

- A function that **converts a number between 0 and 15 into the equivalent hex digit**:

```
char digit_to_hex_char(int digit)
{
    return "0123456789ABCDEF"[digit];
}
```

Operations on String Literals (cont.)

- Attempting to modify a string literal causes undefined behavior:

```
char *p = "abc";
```

```
*p = 'd';    /*** WRONG ***/
```

- A program that tries to change a string literal **may crash** or **behave erratically**.

String Literals versus Character Constants

- A string literal containing a single character isn't the same as a character constant.

- `"a"` is represented by *a pointer (`char *`)*.

- `'a'` is represented by *an integer*.

- A **legal call** of `printf`:

```
printf("\n");
```

- An **illegal call**:

```
printf('\n');    /* ** WRONG ** */
```

10.2 String Variables

String Variables

- Any one-dimensional array of characters can be used to store a string.
- A string must be terminated by a null character.
- Difficulties with this approach:
 - It can be hard to tell whether an array of characters is being used as a string.
 - String-handling functions must be careful to deal properly with the null character.
 - Finding the length of a string requires searching for the null character.

String Variables (cont.)

- If a string variable needs to hold **80 characters**, it **must** be declared to **have length 81**:

```
#define STR_LEN 80
```

```
...
```

```
char str[STR_LEN+1];
```

- **Adding 1** to the desired length **allows room for the null character** at the end of the string.
- **Defining a macro** that represents 80 and **then adding 1** separately **is a common practice**.

String Variables (cont.)

- Be sure to leave room for the null character when declaring a string variable.
- Failing to do so may cause unpredictable results when the program is executed.
- The actual length of a string depends on the position of the terminating null character.
- An array of `STR_LEN + 1` characters can hold strings with lengths between 0 and `STR_LEN`.

Initializing a String Variable

- A string variable **can be initialized** at the same time it's **declared**:

```
char date1[8] = "June 14";
```

- The **compiler will automatically add a null character** so that `date1` can be used as a string:

date1	J	u	n	e		1	4	\0
-------	---	---	---	---	--	---	---	----

Initializing a String Variable (cont.)

- If the initializer is too short to fill the string variable, the compiler adds extra null characters:

```
char date2[9] = "June 14";
```

Appearance of date2:

Initializing a String Variable (cont.)

- An **initializer** for a string variable **can't be longer than the variable**, but it **can be the same length**:

```
char date3[7] = "June 14";
```

- There's **no room for the null character**, so the **compiler makes no attempt to store one**:

Initializing a String Variable (cont.)

- The **declaration** of a string variable **may omit its length**, in which case the **compiler computes it**:

```
char date4[] = "June 14";
```
- The **compiler sets aside eight characters** for `date4`, **enough to store the characters** in `"June 14"` **plus a null character**.
- **Omitting the length** of a string variable **is especially useful if the initializer is long**, since computing the length by hand is error-prone.

Character Arrays versus Character Pointers

- The declaration

```
char date[] = "June 14";
```

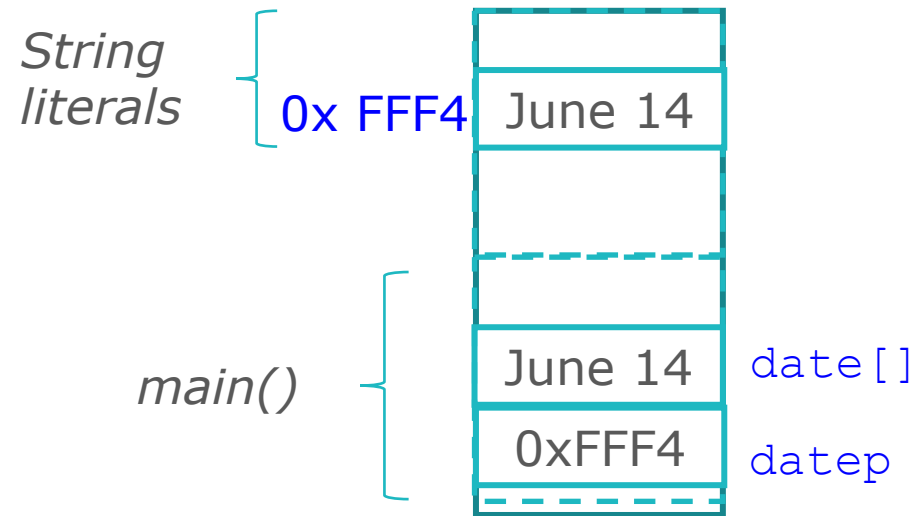

declares `date` to be **an array**,

- The similar-looking

```
char *datep = "June 14";
```

declares `datep` to be **a pointer**.

- Thanks to the close relationship between arrays and pointers, **either version can be used as a string**.

Character Arrays versus Character Pointers (cont.)

- However, there are **significant differences** between the two versions of `date`.
- In the **array version**, the **characters stored in `date` can be modified**.
In the **pointer version**, `datep` points to a string literal that **shouldn't be modified**.
- In the **array version**, `date` is an array name.
In the **pointer version**, `datep` is a variable that **can point to other strings**.

字元陣列可修改

字串常量, 內部元素不能改

Character Arrays versus Character Pointers (cont.)

- The declaration

```
char *p;
```

does not allocate space for a string.

- Before we can use `p` as a string, it must point to an array of characters.
- One possibility is to make `p` point to a string variable:

```
char str[STR_LEN+1], *p;  
p = str;
```
- Another possibility is to make `p` point to a dynamically allocated string.

Character Arrays versus Character Pointers (cont.)

- Using an uninitialized pointer variable as a string is a serious error.
- An attempt at building the string "abc":

```
char *p;
```

```
p[0] = 'a';      /* ** WRONG ** */  
p[1] = 'b';      /* ** WRONG ** */  
p[2] = 'c';      /* ** WRONG ** */  
p[3] = '\\0';    /* ** WRONG ** */
```

- Since `p` hasn't been initialized, this causes undefined behavior.

Accessing the Characters in a String

- Since strings are stored as arrays, **we can use subscripting to access the characters** in a string.
- **To process every character** in a string `s`, **we can set up a loop** that increments a counter `i` and selects characters via the expression `s[i]`.
- A function that **counts the number of spaces** in a string:

```
int count_spaces(const char s[])
{
    int count = 0, i;
    for (i = 0; s[i] != '\0'; i++)
        if (s[i] == ' ')
            count++;
    return count;
}
```

Accessing the Characters in a String (cont.)

- A version that **uses pointer arithmetic instead of array subscripting** :

```
int count_spaces(const char *s)
{
    int count = 0;

    for (; *s != '\0'; s++)
        if (*s == ' ')
            count++;
    return count;
}
```

```
int count_spaces(const char s[])
{
    int count = 0, i;
    for (i = 0; s[i] != '\0'; i++)
        if (s[i] == ' ')
            count++;
    return count;
}
```

Accessing the Characters in a String (cont.)

- Questions raised by the `count_spaces` example:
 - *Is it better to use array operations or pointer operations to access the characters in a string?*
 - > We can use either or both. Traditionally, C programmers lean toward using pointer operations.
 - *Should a string parameter be declared as an array or as a pointer?*
 - > There's no difference between the two.
 - *Does the form of the parameter (`s[]` or `*s`) affect what can be supplied as an argument?*
 - > No.

10.3 Reading and Writing Strings

Reading and Writing Strings

- Writing a string is easy using either `printf` or `puts`.
- Reading a string is a bit harder, because the input may be longer than the string variable into which it's being stored.
- To read a string in a single step, we can use either `scanf` or `gets`.
- As an alternative, we can read strings one character at a time.

Writing Strings Using `printf` and `puts`

- The `%s` conversion specification allows `printf` to write a string:

```
char str[] = "Are we having fun yet?";
```

```
printf("%s\n", str);
```

The output will be

Are we having fun yet?

- `printf` writes the characters in a string one by one until it encounters a null character.

Writing Strings Using `printf` and `puts` (cont.)

- To **print part of a string**, use the conversion specification `%.ps`.
- ***p*** is the **number of characters** to be displayed.
- The statement

```
printf("%.6s\n", str);
```

will print

Are we

Writing Strings Using `printf` and `puts` (cont.)

- The `%ms` conversion will display a string in a field of size `m`.
- If the string has fewer than `m` characters, it will be right-justified within the field.
- To force left justification instead, we can put a minus sign in front of `m`.
- The `m` and `p` values can be used in combination.
- A conversion specification of the form `%m.ps` causes the first `p` characters of a string to be displayed in a field of size `m`.

Writing Strings Using `printf` and `puts` (cont.)

- `printf` isn't the only function that can write strings.
- The C library also provides `puts`:

```
puts(str);
```

✎ After writing a string, `puts` always writes an additional new-line character.

Reading Strings Using `scanf` and `gets`

- The `%s` conversion specification allows `scanf` to read a string into a character array:

```
scanf("%s", str);
```
- `str` is treated as a pointer, so there's no need to put the `&` operator in front of `str`.
- When `scanf` is called, it skips white space, then reads characters and stores them in `str` until it encounters a white-space character.
- `scanf` always stores a null character at the end of the string.

Reading Strings Using `scanf` and `gets` (cont.)

- `scanf` won't usually read a full line of input.
- A new-line character will cause `scanf` to stop reading, but so will a space or tab character.
- To read an entire line of input, we can use `gets`.
- Properties of `gets`:
 - Doesn't skip white space before starting to read input.
 - Reads until it finds a new-line character.
 - Discards the new-line character instead of storing it; the null character takes its place.

Reading Strings Using `scanf` and `gets` (cont.)

- Consider the following program fragment:

```
char sentence[SENT_LEN+1];  
  
printf("Enter a sentence:\n");  
scanf("%s", sentence);
```

- Suppose that after the prompt

Enter a sentence:

the user enters the line

To C, or not to C: that is the question.

- `scanf` will store the string "To" in sentence.

Reading Strings Using `scanf` and `gets` (cont.)

- Suppose that we **replace** `scanf` **by** `gets`:
`gets(sentence);`
- When the user enters the same input as before, `gets` **will store the string**
`" To C, or not to C: that is the question."`
in `sentence`.

Reading Strings Using `scanf` and `gets` (cont.)

- As they read characters into an array, `scanf` and `gets` have no way to detect when it's full.
- Consequently, they may store characters past the end of the array, causing undefined behavior.
- `scanf` can be made safer by using the conversion specification `%ns` instead of `%s`.
- `n` is an integer indicating the maximum number of characters to be stored.
- `gets` is inherently unsafe; `fgets` is a much better alternative.

Reading Strings Character by Character (cont.)

- Programmers often write their own input functions.
- Issues to consider:
 - Should the function skip white space before beginning to store the string?
 - What character causes the function to stop reading: a new-line character, any white-space character, or some other character? Is this character stored in the string or discarded?
 - What should the function do if the input string is too long to store: discard the extra characters or leave them for the next input operation?

Reading Strings Character by Character (cont.)

- Suppose we need a function that (1) doesn't skip white-space characters, (2) stops reading at the first new-line character (which isn't stored in the string), and (3) discards extra characters.
- A prototype for the function:

```
int read_line(char str[], int n);
```
- If the input line contains more than `n` characters, `read_line` will discard the additional characters.
- `read_line` will return the number of characters it stores in `str`.

Reading Strings Character by Character (cont.)

- `read_line` consists primarily of a loop that calls `getchar` to read a character and then stores the character in `str`, provided that there's room left:

```
int read_line(char str[], int n)
{
    int ch, i = 0;

    while ((ch = getchar()) != '\n')
        if (i < n)
            str[i++] = ch;
    str[i] = '\0';    /* terminates string */
    return i;         /* number of characters stored */
}
```

- `ch` has `int` type rather than `char` type because `getchar` returns an `int` value.

Reading Strings Character by Character (cont.)

- Before returning, `read_line` puts a null character at the end of the string.
- Standard functions such as `scanf` and `gets` automatically put a null character at the end of an input string.
- If we're writing our own input function, we must take on that responsibility.

10.4 Using the C String Library

Using the C String Library

- Some programming languages provide operators that can copy strings, compare strings, concatenate strings, select substrings, and the like.
- C's operators, in contrast, are essentially useless for working with strings.
- Strings are treated as arrays in C, so they're restricted in the same ways as arrays.
- In particular, they can't be copied or compared using operators.

Using the C String Library (cont.)

- Copying a string into a character array using the = operator is not possible:

```
char str1[10], str2[10];
```

```
...
```

```
str1 = "abc";    /*** WRONG ***/
```

```
str2 = str1;     /*** WRONG ***/
```

Using an array name as the left operand of = is illegal.

- *Initializing* a character array using = is legal, though:

```
char str1[10] = "abc";
```

In this context, = is not the assignment operator.

Using the C String Library (cont.)

- Attempting to **compare strings** using a **relational** or **equality** operator is legal but won't produce the desired result:

```
if (str1 == str2) ...    /*** WRONG ***/
```

- This statement **compares** `str1` and `str2` as *pointers*.
- Since `str1` and `str2` have different addresses, the expression `str1 == str2` must have the value 0.

Using the C String Library (cont.)

- The **C library** provides a rich set of functions for performing operations on **strings**.
- Programs that need string operations should contain the following line:

```
#include <string.h>
```
- In subsequent examples, assume that `str1` and `str2` are character arrays used as strings.

The `strcpy` (String Copy) Function

- **Prototype** for the `strcpy` function:
`char *strcpy(char *s1, const char *s2);`
- `strcpy` **copies** the **string** `s2` **into** the **string** `s1`.
 - To be precise, we should say “`strcpy` copies the string pointed to by `s2` into the array pointed to by `s1`.”
- `strcpy` **returns** `s1` (a pointer to the destination string).

The strcpy (String Copy) Function (cont.)

- A call of `strcpy` that stores the string "abcd" in `str2`:

```
strcpy(str2, "abcd");
```

```
/* str2 now contains "abcd" */
```
- A call that copies the contents of `str2` into `str1`:

```
strcpy(str1, str2);
```

```
/* str1 now contains "abcd" */
```
- In the call `strcpy(str1, str2)`, **strcpy has no way to check** that the **str2 string will fit** in the array pointed to by `str1`.
- **If it doesn't, undefined behavior occurs.**

The `strncpy` (String Copy) Function

- Calling the `strncpy` function is a safer, albeit slower, way to copy a string.
- `strncpy` has a third argument that limits the number of characters that will be copied.
- `strncpy` will leave `str1` without a terminating null character if the length of `str2` is greater than or equal to the size of the `str1` array.
- A safer way to use `strncpy`:

```
strncpy(str1, str2, sizeof(str1) - 1);  
str1[sizeof(str1)-1] = '\0';
```
- The second statement guarantees that `str1` is always null-terminated.

The `strlen` (String Length) Function

- Prototype for the `strlen` function:

```
size_t strlen(const char *s);
```

- `size_t` is a typedef name that represents one of C's unsigned integer types.
- `strlen` returns the length of a string `s`, not including the null character.

- Examples:

```
int len;
```

```
len = strlen("abc"); /* len is now 3 */
```

```
len = strlen(""); /* len is now 0 */
```

```
strcpy(str1, "abc");
```

```
len = strlen(str1); /* len is now 3 */
```

The `strcat` (String Concatenation) Function

- Prototype for the `strcat` function:

```
char *strcat(char *s1, const char *s2);
```

- `strcat` **appends** the contents of the **string** `s2` **to** the **end of** the **string** `s1`.
- It **returns** `s1` (a pointer to the **resulting string**).
- `strcat` **examples**:

```
strcpy(str1, "abc");  
strcat(str1, "def");  
/* str1 now contains "abcdef" */  
strcpy(str1, "abc");  
strcpy(str2, "def");  
strcat(str1, str2);  
/* str1 now contains "abcdef" */
```

The `strcat` (String Concatenation) Function (cont.)

- As with `strcpy`, the value returned by `strcat` is normally discarded.
- The following example shows how the return value might be used:

```
strcpy(str1, "abc");  
strcpy(str2, "def");  
strcat(str1, strcat(str2, "ghi"));  
/* str1 now contains "abcdefghi";  
   str2 contains "defghi" */
```

The `strcat` (String Concatenation) Function (cont.)

- `strcat(str1, str2)` causes **undefined behavior** if the **`str1` array isn't long enough** to accommodate the characters from `str2`.
- Example:

```
char str1[6] = "abc";  
  
strcat(str1, "def");    /*** WRONG ***/
```
- `str1` is limited to six characters, causing `strcat` to write past the end of the array.

The `strncat` (String Concatenation) Function

- The `strncat` function is a **safer but slower** version of `strcat`.
- **Like `strncpy`**, it has **a third argument** that **limits the number of characters** it will copy.
- A call of `strncat`:

```
strncat(str1, str2, sizeof(str1) - strlen(str1) - 1);
```
- `strncat` **will terminate** `str1` **with a null character**, which **isn't included in the third argument**.

The strcmp (String Comparison) Function

- Prototype for the strcmp function:

```
int strcmp(const char *s1, const char *s2);
```

- strcmp **compares** the strings **s1** and **s2**, returning a value **less than, equal to, or greater than 0**, depending on whether **s1** is less than, equal to, or greater than **s2**.
- **Testing** whether **str1** is less than **str2**:

```
if (strcmp(str1, str2) < 0)    /* is str1 < str2? */
```
- **Testing** whether **str1** is less than or equal to **str2**:

```
if (strcmp(str1, str2) <= 0) /* is str1 <= str2? */
```
- By choosing the proper operator (**<**, **<=**, **>**, **>=**, **==**, **!=**), **we can test any possible relationship** between **str1** and **str2**.

The strcmp (String Comparison) Function (cont.)

- As it compares two strings, **strcmp** looks at the numerical codes for the characters in the strings.
- Important properties of ASCII:
 - A–Z, a–z, and 0–9 have consecutive codes.
 - All upper-case letters are less than all lower-case letters.
 - Digits are less than letters.
 - Spaces are less than all printing characters.

ASCII value	Character	ASCII value	Character	ASCII value	Character
000	~@	043	+	086	V
001	~A	044	,	087	W
002	~B	045	-	088	X

041)	084	T	127	DEL
042	*	085	U		

The `strcmp` (String Comparison) Function (cont.)

- `strcmp` considers `s1` to be less than `s2` if either one of the following conditions is satisfied:
 - The first i characters of `s1` and `s2` match, but the $(i+1)$ st character of `s1` is less than the $(i+1)$ st character of `s2`.
 - All characters of `s1` match `s2`, but `s1` is shorter than `s2`.

"abc" < "abd"

"abc" < "abcd"

Program: Printing a One-Month Reminder List

- The `remind.c` program prints a **one-month list of daily reminders**.
- The **user will enter a series of reminders**, with each **prefixed by a day** of the month.
- When the **user enters 0** instead of a valid day, the program will **print a list of all reminders** entered, **sorted by day**.
- The next slide shows a session with the program.

Program: Printing a One-Month Reminder List (cont.)

```
Enter day and reminder: 24 Susan's birthday
Enter day and reminder: 5 6:00 - Dinner with Marge and Russ
Enter day and reminder: 26 Movie - "Chinatown"
Enter day and reminder: 7 10:30 - Dental appointment
Enter day and reminder: 12 Movie - "Dazed and Confused"
Enter day and reminder: 5 Saturday class
Enter day and reminder: 12 Saturday class
Enter day and reminder: 0
```

Day Reminder

```
5 Saturday class
5 6:00 - Dinner with Marge and Russ
7 10:30 - Dental appointment
12 Saturday class
12 Movie - "Dazed and Confused"
24 Susan's birthday
26 Movie - "Chinatown"
```

Program: Printing a One-Month Reminder List (cont.)

- Overall strategy:
 - **Read** a series of day-and-reminder combinations.
 - **Store them in order** (sorted by day).
 - **Display** them.
- `scanf` will be used to **read the days**.
- `read_line` will be used to **read the reminders**.

Program: Printing a One-Month Reminder List (cont.)

- The **strings** will be **stored in a two-dimensional array** of characters.
- **Each row** of the array **contains one string**.
- Actions taken after the program reads a day and its associated reminder:
 - **Search the array** to determine where the day belongs, **using `strcmp` to do comparisons**.
 - **Use `strcpy` to move all strings below that point** down one position.
 - **Copy the day into the array and call `strcat` to append the reminder to the day**.

Program: Printing a One-Month Reminder List (cont.)

- One complication: **how to right-justify the days** in a two-character field.
- A solution: **use `scanf` to read the day into an integer variable**, then **call `sprintf` to convert** the day back into string form.
- `sprintf` is **similar to `printf`**, except that it writes **output into a string**.
- The following call **writes the value of `day` into `day_str`**.

```
sprintf(day_str, "%2d", day);
```
- The following call of `scanf` **ensures that the user doesn't enter more than two digits**:

```
scanf("%2d", &day);
```

Program: Printing a One-Month Reminder List (cont.)

```
#include <stdio.h>                                remind.c
#include <string.h>
#define MAX_REMIND 50    /* maximum number of reminders */
#define MSG_LEN 60       /* max length of reminder message */
int read_line(char str[], int n);
int main(void)
{
    char reminders[MAX_REMIND][MSG_LEN+3];
    char day_str[3], msg_str[MSG_LEN+1];
    int day, i, j, num_remind = 0;

    for (;;) {
        if (num_remind == MAX_REMIND) {
            printf("-- No space left --\n");
            break;
        }
        printf("Enter day and reminder: ");
        scanf("%2d", &day);
        if (day == 0)
            break;
        sprintf(day_str, "%2d", day);
        read_line(msg_str, MSG_LEN);
    }
}
```

Program: Printing a One-Month Reminder List (cont.)

```
for (i = 0; i < num_remind; i++)
    if (strcmp(day_str, reminders[i]) < 0)
        break;
for (j = num_remind; j > i; j--)
    strcpy(reminders[j], reminders[j-1]);

strcpy(reminders[i], day_str);
strcat(reminders[i], msg_str);
num_remind++;
}

printf("\nDay Reminder\n");
for (i = 0; i < num_remind; i++)
    printf(" %s\n", reminders[i]);

return 0;
}
```

```
int read_line(char str[], int n)
{
    int ch, i = 0;

    while ((ch = getchar()) != '\n')
        if (i < n)
            str[i++] = ch;
    str[i] = '\0';
    return i;
}
```

The `strtok` (String Token) Function

- Prototype for the `strtok` function:

```
char* strtok(char *str, const char *sep);
```

- `strtok` **isolates sequential tokens** in the string `str`. These tokens are separated by at least one of the characters in `sep`.
- The **first time** that `strtok()` is called, `str` **should be specified; subsequent calls**, wishing to obtain further tokens **from the same string**, should **pass a null pointer** instead.
- The separator string, `sep`, **must be supplied each time**, and may change between calls.

Program: Separating Each Sentence

`sep_sentence.c`

```
#include <stdio.h>
#include <string.h>

int main()
{
    char str[80] = "Hi, I am Biden. Nice to meet you. Bye.";
    char * token;

    token = strtok(str, ".");
    while(token != NULL) {
        printf("%s\n", token);
        token = strtok(NULL, ".");
    }

    return 0;
}
```

```
$ ./sep_sentence
Hi, I am Biden
Nice to meet you
Bye
```

10.5 Arrays of Strings

Arrays of Strings

- There is **more than one way** to store an array of **strings**.
- One option is to use **a two-dimensional array of characters**, with one string per row:

```
char planets[][8] = {"Mercury", "Venus", "Earth",  
                    "Mars", "Jupiter", "Saturn",  
                    "Uranus", "Neptune", "Pluto"};
```

- The **number of rows** in the array **can be omitted**, but we **must specify the number of columns**.

Arrays of Strings (cont.)

- Unfortunately, the `planets` array contains a fair bit of wasted space (extra null characters):

	0	1	2	3	4	5	6	7
0	M	e	r	c	u	r	y	\0
1	V	e	n	u	s	\0	\0	\0
2	E	a	r	t	h	\0	\0	\0
3	M	a	r	s	\0	\0	\0	\0
4	J	u	p	i	t	e	r	\0
5	S	a	t	u	r	n	\0	\0
6	U	r	a	n	u	s	\0	\0
7	N	e	p	t	u	n	e	\0
8	P	l	u	t	o	\0	\0	\0

Arrays of Strings (cont.)

- Most collections of strings will have a mixture of long strings and short strings.
- What we need is a **ragged array**, whose **rows** can have **different lengths**.
- We can simulate a ragged array in C by creating an array whose elements are **pointers to strings**:

```
char *planets[] = {"Mercury", "Venus", "Earth",  
                  "Mars", "Jupiter", "Saturn",  
                  "Uranus", "Neptune", "Pluto"};
```

Arrays of Strings (cont.)

- This small change has a dramatic effect on how `planets` is stored:

Arrays of Strings (cont.)

- To access one of the planet names, all we need do is subscript the `planets` array.
- Accessing a character in a planet name is done in the same way as accessing an element of a two-dimensional array.
- A loop that searches the `planets` array for strings beginning with the letter M:

```
for (i = 0; i < 9; i++)  
    if (planets[i][0] == 'M')  
        printf("%s begins with M\n", planets[i]);
```

Command-Line Arguments

- When we run a program, we'll often need to supply it with information.
- This may include a file name or a switch that modifies the program's behavior.
- Examples of the UNIX `ls` command:

```
ls
```

```
ls -l
```

```
ls -l remind.c
```

Command-Line Arguments (cont.)

- Command-line information is available to all programs, not just operating system commands.
- To obtain access to **command-line arguments**, `main` must have two parameters:

```
int main(int argc, char *argv[])  
{  
    ...  
}
```

- Command-line arguments are called **program parameters** in the C standard.

Command-Line Arguments (cont.)

- `argc` ("argument **count**") is the number of command-line arguments.
- `argv` ("argument **vector**") is an array of pointers to the command-line arguments (stored as strings).
- `argv[0]` points to the **name of the program**, while `argv[1]` **through** `argv[argc-1]` point to the **remaining** command-line arguments.
- `argv[argc]` is **always a *null pointer***—a special pointer that points to nothing.
 - The macro `NULL` represents a null pointer.

Command-Line Arguments (cont.)

- If the user enters the command line

```
ls -l remind.c
```

then `argc` will be 3, and `argv` will have the following appearance:

Command-Line Arguments (cont.)

- Typically, a program that expects command-line arguments will set up a loop that examines each argument in turn.
- One way to write such a loop is to use an integer variable as an index into the `argv` array:

```
int i;  
for (i = 1; i < argc; i++)  
    printf("%s\n", argv[i]);
```

- Another technique is to set up a pointer to `argv[1]`, then increment the pointer repeatedly:

```
char **p;  
for (p = &argv[1]; *p != NULL; p++)  
    printf("%s\n", *p);
```

Program: Checking Planet Names

- The `planet.c` program illustrates how to access command-line arguments.
- The program is designed to check a series of strings to see which ones are names of planets.
- The strings are put on the command line:
- The program will indicate whether each string is a planet name and, if it is, display the planet's number:

```
planet Jupiter venus Earth fred
```

```
Jupiter is planet 5  
venus is not a planet  
Earth is planet 3  
fred is not a planet
```

Program: Checking Planet Names (cont.)

planet.c

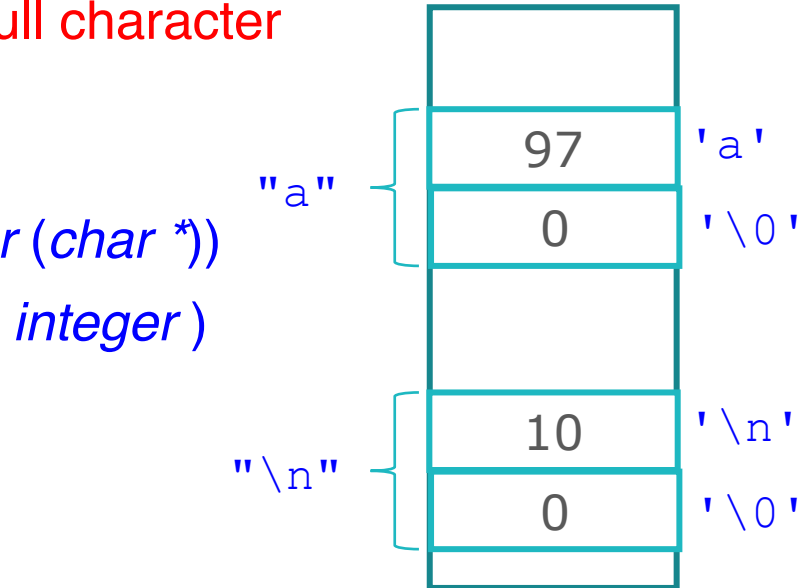

```
#include <stdio.h>
#include <string.h>
#define NUM_PLANETS 9
int main(int argc, char *argv[])
{
    char *planets[] = {"Mercury", "Venus", "Earth",
                       "Mars", "Jupiter", "Saturn",
                       "Uranus", "Neptune", "Pluto"};

    int i, j;
    for (i = 1; i < argc; i++) {
        for (j = 0; j < NUM_PLANETS; j++)
            if (strcmp(argv[i], planets[j]) == 0) {
                printf("%s is planet %d\n", argv[i], j + 1);
                break;
            }
        if (j == NUM_PLANETS)
            printf("%s is not a planet\n", argv[i]);
    }

    return 0;
}
```

A Quick Review to This Lecture

- Strings are **arrays of characters** in which the **null character** marks the end (an **extra byte** is required).
- String Literals
 - String Literals: "a" (represented by *a pointer (char *)*)
 - Character Constants: 'a' (represented by *an integer*)
 - String literals can be **subscripted**:
char ch = "abc"[1];
- String Variables:

- Be sure to leave room for the null character

```
char date1[8] = "June 14";
```

- Length can be omitted

```
char date1[] = "June 14";
```

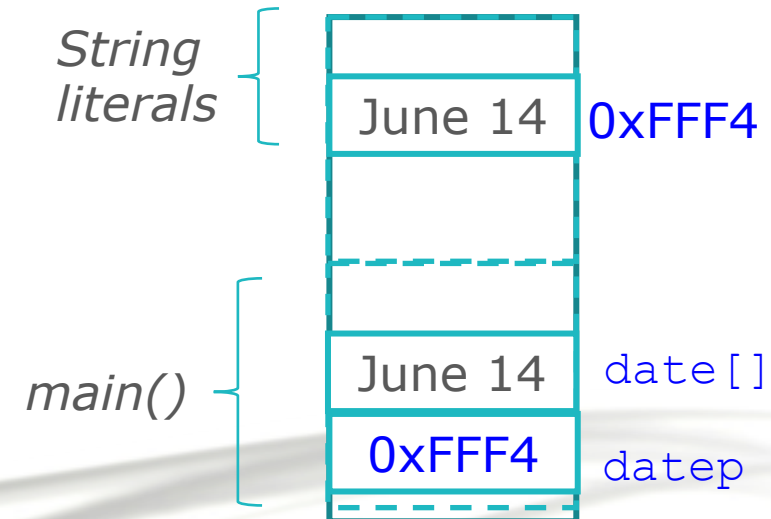

A Quick Review to This Lecture (cont.)

- Character array vs. character pointer

Character array	Character pointer
<code>char date[] = "June 14";</code>	<code>char *datep = "June 14";</code>
Allocate space	Does not allocate space
Characters can be modified	Characters can not be modified

- Writing strings: `printf` / `puts`
- Reading strings: `scanf` / `gets` / `fgets`
- Reading a character: `getchar`

A Quick Review to This Lecture (cont.)

- `printf("%m.ps", str);`
 - `%m.ps`: display first p characters in a field of size m (right justified)
 - `%-m.ps`: display first p characters in a field of size m (left justified)
- `puts(str);` // always writes an additional new-line character

A Quick Review to This Lecture (cont.)

- `scanf ("%ns", str);`
- `%ns`: `n` indicates the maximum number of stored characters
- skips leading white spaces, **reads**, and stops reading while encountering a white space or `n` characters are read
- `gets(str);`
- Do not skip leading white spaces, **reads**, and stops reading only when encountering a new-line character
- `fgets(str, n, stdin);`

A Quick Review to This Lecture (cont.)

- C String Library (`#include <string.h>`)
 - `strcpy` / `strncpy` **copies the string `s2` into the string `s1`, and returns `s1`**
`char *strcpy(char *s1, const char *s2);` `strcpy(str2, "abcd");`
`char *strncpy(char *s1, const char *s2, size_t n);`
`strncpy(str1, str2, sizeof(str1) - 1);`
`str1[sizeof(str1)-1] = '\0';`
 - `strlen` **returns the length of a string `s`, not including the null character.**
`size_t strlen(const char *s);` `len = strlen("abc"); // 3`
 - `strcat` / `strncat` **appends the string `s2` to the end of string `s1`, and returns `s1`**
`char *strcat(char *s1, const char *s2);` `strcat(str1, "def");`
`char *strncat(char *s1, const char *s2, size_t n);`
`strncat(str1, str2, sizeof(str1) - strlen(str1) - 1);`

A Quick Review to This Lecture (cont.)

- `strcmp` **compares** the strings `s1` and `s2`, returning a **negative** value, **zero** or a **positive** value if `s1` is less than, equal to, or greater than `s2`.

```
int strcmp(const char *s1, const char *s2);
```

```
if (strcmp(str1, str2) < 0) /* is str1 < str2? */
```

`s1` is less than `s2` if **one** of the following conditions is satisfied:

- The first *i* characters of `s1` and `s2` match, but the (*i*+1)st character of `s1` is less than the (*i*+1)st character of `s2`. "abc" < "abd"

- All characters of `s1` match `s2`, but `s1` is shorter than `s2`.

"abc" < "abcd"

- `sprintf` is **similar to** `printf`, but writes **output into a string**.

```
sprintf(day_str, "%2d", day);
```

A Quick Review to This Lecture (cont.)

- `strtok` isolates sequential tokens in the string `str`. These tokens are separated by at least one of the characters in `sep`.
`char* strtok(char *str, const char *sep);`
- The first time that `strtok()` is called, `str` should be specified; subsequent calls, wishing to obtain further tokens from the same string, should pass a null pointer instead.
- The separator string, `sep`, must be supplied each time, and may change between calls.

```
token = strtok(str, ".");  
while(token != NULL) {  
    printf("%s\n", token);  
    token = strtok(NULL, ".");  
}
```

A Quick Review to This Lecture (cont.)

- To obtain access to **command-line arguments**, `main` must have two parameters:

```
int main(int argc, char *argv[])
```

- If the user enters the command line

```
ls -l remind.c
```

then `argc` will be **3**, and `argv` will have the following appearance:
